# Maximum Coverage over a Matroid Constraint

Yuval Filmus Justin Ward University of Toronto

China Theory Week 2011

# Max Coverage: History

- Location of bank accounts: Cornuejols, Fisher & Nemhauser 1977, Management Science
- Official definition: Hochbaum & Pathria 1998, Naval Research Quarterly
- Lower bound: Feige 1998
- Extended to Submodular Max. over a Matroid: Calinescu, Chekuri, Pál & Vondrák 2008 (with help from Ageev & Sviridenko 2004)

We consider Maximum Coverage over a Matroid.

# Maximum Coverage ...

#### Input:

- Universe *U* with weights  $w \ge 0$
- Sets  $S_i \subset U$
- Number n

#### Goal:

• Find *n* sets  $S_i$  that maximize  $w(S_{i_1} \cup \cdots \cup S_{i_n})$ 

# Maximum Coverage ...

#### Input:

- Universe *U* with weights  $w \ge 0$
- Sets  $S_i \subset U$
- Number n

Goal:

• Find *n* sets  $S_i$  that maximize  $w(S_{i_1} \cup \cdots \cup S_{i_n})$ 

Greedy algorithm gives 1 - 1/e approximation. Feige ('98): optimal unless P=NP.

#### Input:

- Universe *U* with weights  $w \ge 0$
- Sets  $S_i \subset U$
- Matroid m over set of all S<sub>i</sub>

Goal:

# Find collection of sets S ∈ m that maximizes w(∪S)

### What is a matroid?

Invented by Whitney (1935).

#### **Definition: Matroid**

A collection of *independent sets* s.t.

- A independent,  $B \subset A \Rightarrow B$  independent.
- ② *A*, *B* independent,  $|A| > |B| \Rightarrow$  there exists some *x* ∈ *A* \ *B* s.t. *B* ∪ *x* is independent.

Invented by Whitney (1935).

#### **Definition: Matroid**

A collection of *independent sets* s.t.

- A independent,  $B \subset A \Rightarrow B$  independent.
- ② *A*, *B* independent,  $|A| > |B| \Rightarrow$  there exists some *x* ∈ *A* \ *B* s.t. *B* ∪ *x* is independent.

#### **Partition Matroid**

- $\mathcal{F}_1, \ldots, \mathcal{F}_n$  disjoint sets.
- Independent set:  $\leq 1$  set from each  $\mathcal{F}_i$ .

# Max Coverage over a Partition Matroid

#### Input:

- Universe *U* with weights  $w \ge 0$
- *n* families  $\mathcal{F}_i \subset 2^U$

#### Goal:

Find collection of sets S<sub>i</sub> ∈ F<sub>i</sub> that maximizes w(S<sub>1</sub> ∪ · · · ∪ S<sub>n</sub>)

#### n is the rank of the matroid.

# Some algorithms

#### Greedy

- Pick set  $S_1$  of maximal weight.
- **2** Pick set  $S_2$  of maximal *additional* weight.
- And so on.

# Some algorithms

#### Greedy

- Pick set  $S_1$  of maximal weight.
- **2** Pick set  $S_2$  of maximal *additional* weight.
- And so on.

#### Local Search

- Start at some solution  $S_1, \ldots, S_n$ .
- Replace some S<sub>i</sub> with some S'<sub>i</sub> that improves total weight.
  - Repeat Step 2 while possible.

# Failure of greedy

#### Bad instance for Greedy

Greedy chooses  $\{A_1, B\}$ , optimal is  $\{A_2, B\}$ .

Resulting approximation ratio is only 1/2.

# Failure of greedy

#### Bad instance for Greedy

Greedy chooses  $\{A_1, B\}$ , optimal is  $\{A_2, B\}$ .

Resulting approximation ratio is only 1/2.

Local search finds optimal solution.

### Maybe local search?

#### Bad instance for Local Search

$$A_{1} = \{x, \epsilon_{x}\} \qquad B_{1} = \{x\}$$
$$\frac{A_{2} = \{y\}}{\mathcal{F}_{1}} \qquad \frac{B_{2} = \{\epsilon_{y}\}}{\mathcal{F}_{2}}$$
$$w(x) = w(y) \gg w(\epsilon_{x}) = w(\epsilon_{y})$$

 $\{A_1, B_2\}$  is local maximum. Optimum is  $\{A_2, B_1\}$ .

### Maybe local search?

#### Bad instance for Local Search

$$A_{1} = \{x, \epsilon_{x}\} \qquad B_{1} = \{x\}$$
$$A_{2} = \{y\} \qquad B_{2} = \{\epsilon_{y}\}$$
$$\mathcal{F}_{1} \qquad \mathcal{F}_{2} \qquad \mathcal{F}_{2}$$
$$w(x) = w(y) \gg w(\epsilon_{x}) = w(\epsilon_{y})$$

 $\{A_1, B_2\}$  is local maximum. Optimum is  $\{A_2, B_1\}$ . *k*-local search (on SBO matroids) has approx ratio

$$\frac{1}{2} + \frac{k-1}{2n-k-1}$$

$$\begin{array}{ll} A_1 = \{x, \, \epsilon_x\} & B_1 = \{x\} \\ A_2 = \{y\} & B_2 = \{\epsilon_y\} \end{array}$$

#### Fantasy algorithm

$$A_{1} = \{x, \epsilon_{x}\} \quad B_{1} = \{x\}$$
$$A_{2} = \{y\} \quad B_{2} = \{\epsilon_{y}\}$$
$$x \times 1$$
$$\epsilon_{x} \times 1$$

Greedy stage

$$A_{1} = \{x, \epsilon_{x}\} \quad B_{1} = \{x\}$$

$$A_{2} = \{y\} \quad B_{2} = \{\epsilon_{y}\}$$

$$x \times 1$$

$$\epsilon_{x} \times 1$$

$$\epsilon_{y} \times 1$$

Greedy stage

$$A_{1} = \{x, \epsilon_{x}\} \quad B_{1} = \{x\}$$
$$A_{2} = \{y\} \quad B_{2} = \{\epsilon_{y}\}$$
$$x \times 2$$
$$\epsilon_{x} \times 1$$

Local search stage

We lose  $\epsilon_y$  but gain second appearance of *x*.

$$A_{1} = \{x, \epsilon_{x}\} \quad B_{1} = \{x\}$$
$$A_{2} = \{y\} \quad B_{2} = \{\epsilon_{y}\}$$
$$x \times 1$$
$$y \times 1$$

#### Local search stage

$$A_{1} = \{x, \epsilon_{x}\} \quad B_{1} = \{x\}$$
$$A_{2} = \{y\} \quad B_{2} = \{\epsilon_{y}\}$$
$$x \times 1$$
$$y \times 1$$

#### Done — found optimal solution

### Non-oblivious local search

#### Idea

Give more weight to duplicate elements.

Use local search with auxiliary objective function (Alimonti '94; Khanna, Motwani, Sudan & U. Vazirani '98):

$$f(\mathcal{S}) = \sum_{u \in U} lpha_{\#_u(\mathcal{S})} w(u).$$

Change is considered beneficial if it improves f(S). Oblivious local search:  $\alpha_0 = 0$ ,  $\alpha_i = 1$  for  $i \ge 1$ . Consider what happens at termination.

Setup:

- $S_1, \ldots, S_n$ : local maximum.
- $O_1, \ldots, O_n$ : optimal solution.

Local optimality implies (using Brualdi's theorem)

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Parametrize situation using  $w_{l,c,g}$  = total weight of elements which belong to

- I + c sets  $S_i$
- g + c sets  $O_i$
- c of the indices in common

I.e., up to permutation

$$S_1 \cap \cdots \cap S_l \cap S_{l+1} \cap \cdots \cap S_{l+c} \cap O_{l+1} \cap \cdots \cap O_{l+c} \cap O_{l+c+1} \cap \cdots \cap O_{l+c+g}$$

Local optimality implies

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Local optimality implies

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Take some *x*. Let  $L = \{i : x \in S_i\}, G = \{i : x \in O_i\}.$ 

Local optimality implies

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Take some x. Let  $L = \{i : x \in S_i\}, G = \{i : x \in O_i\}.$ 

• Coefficient on the left:  $n\alpha_{|L|}$ 

Local optimality implies

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Take some x. Let  $L = \{i : x \in S_i\}, G = \{i : x \in O_i\}.$ 

- Coefficient on the left:  $n\alpha_{|L|}$
- Coefficient on the right:

 $(|\overline{L \cup G}| + |L \cap G|)\alpha_{|L|} + |L \setminus G| \cdot \alpha_{|L|-1} + |G \setminus L| \cdot \alpha_{|L|+1}$ 

Local optimality implies

$$nf(S_1,...,S_n) \ge \sum_{i=1}^n f(S_1,...,S_{i-1},O_i,S_{i+1},...,S_n)$$

Take some x. Let  $L = \{i : x \in S_i\}, G = \{i : x \in O_i\}.$ 

- Coefficient on the left:  $n\alpha_{|L|}$
- Coefficient on the right:

$$(|\overline{L \cup G}| + |\underline{L \cap G}|)\alpha_{|L|} + |\underline{L \setminus G}| \cdot \alpha_{|L|-1} + |\underline{G \setminus L}| \cdot \alpha_{|L|+1}$$

So local optimality is equivalent to

$$\sum_{l,c,g} \left[ l(\alpha_{l+c} - \alpha_{l+c-1}) + g(\alpha_{l+c} - \alpha_{l+c+1}) \right] w_{l,c,g} \ge 0$$

Local optimality translates to

$$\sum_{l,c,g} \left[ (l+g)\alpha_{l+c} - l\alpha_{l+c-1} - g\alpha_{l+c+1} \right] w_{l,c,g} \ge 0$$

Also,

$$w(O_1,\ldots,O_n) = \sum_{g+c\geq 1} w_{l,c,g} 
onumber \ w(S_1,\ldots,S_n) = \sum_{l+c\geq 1} w_{l,c,g}$$

Approximation ratio  $\theta$  is given by

$$\max_{\alpha_i} \min_{w_{l,c,g}} \sum_{l+c \ge 1} w_{l,c,g}$$

$$\sum_{\substack{g+c\geq 1\\ \sum_{l,c,g}}} w_{l,c,g} = 1$$
$$\sum_{l,c,g} \left[ (l+g)\alpha_{l+c} - l\alpha_{l+c-1} - g\alpha_{l+c+1} \right] w_{l,c,g} \ge 0$$

 $W_{l,c,g} \geq 0$ 

Dualize the inner LP, fix second variable to 1:

 $\max_{\alpha_{i}} \max_{\theta} \theta$ s.t.  $l(\alpha_{l} - \alpha_{l-1}) \leq 1 \quad l \geq 1$  $-g\alpha_{1} \leq -\theta \quad g \geq 1$  $(l+g)\alpha_{l+c} - l\alpha_{l+c-1} - g\alpha_{l+c+1} \leq 1 - \theta$  $c \geq 1 \text{ or } l, g \geq 1$ 

Fold both max's to get an LP for the coefficients  $\alpha_i$ .

# **Optimal weights**

#### Solution to LP is $\theta = 1 - 1/e$ and

$$egin{aligned} &lpha_0 = \mathbf{0}, \ &lpha_1 = heta, \ &lpha_{l+1} = (l+1)lpha_l - llpha_{l-1} - (1- heta). \end{aligned}$$

Sequence monotone concave,  $\alpha_l = \frac{1}{e} \log l + O(1)$ .

# **Optimal weights**

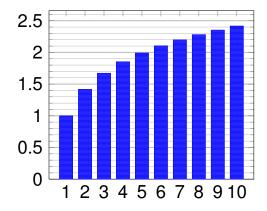

#### Solution to LP is $\theta = 1 - 1/e$ and

$$egin{aligned} lpha_0 &= 0, \ lpha_1 &= heta, \ lpha_{l+1} &= (l+1)lpha_l - llpha_{l-1} - (1- heta). \end{aligned}$$

Sequence monotone concave,  $\alpha_l = \frac{1}{e} \log l + O(1)$ . For rank *n*, can replace *e* with

$$e^{[n]} = \sum_{k=0}^{n-1} \frac{1}{k!} + \frac{1}{(n-1)\cdot(n-1)!} \approx e + \frac{1}{(n+2)!}.$$

# Optimal weights (normalized)

# What now?

#### Conclusion

Optimal combinatorial algorithm for maximum coverage over a matroid.

#### Holy grail

Optimal combinatorial algorithm for monotone submodular maximization over a matroid.

Continuous algorithm by Calinescu, Chekuri, Pál and Vondrák (STOC 2008).

Work in progress. We're hopeful.

### Monotone submodular functions

Monotonicity

$$A \subseteq B \Rightarrow f(A) \leq f(B)$$

### Monotone submodular functions

#### Monotonicity

$$A \subseteq B \Rightarrow f(A) \leq f(B)$$

#### Submodularity

$$f(A \cup B) + f(A \cap B) \leq f(A) + f(B)$$

Discrete analog of *concave*.

# Monotone submodular functions

#### Monotonicity

$$A \subseteq B \Rightarrow f(A) \leq f(B)$$

Submodularity

$$f(A \cup B) + f(A \cap B) \leq f(A) + f(B)$$

Discrete analog of *concave*.

Coverage function is monotone submodular.

# Generalizing the algorithm

Original function depended on *elements*. No longer have elements, so instead use

$$g(S) = \sum_{T \subseteq S} \beta_{|T|} f(T).$$

- *f* is actual objective function (monotone submodular).
- g is objective function used for local search.

If *f* is a coverage function, can recover elements using inclusion-exclusion, so can interpret previous algorithm in new setting. Surprisingly, works for *general* monotone submodular functions up to rank 6. If *f* is a coverage function, can recover elements using inclusion-exclusion, so can interpret previous algorithm in new setting. Surprisingly, works for *general* monotone submodular functions up to rank 6.

Stops working at rank 7 (explicit counterexample). Can calculate optimal coefficients as before. Empirically, still yields 1 - 1/e. Work in progress.

#### Our results:

- Combinatorial algorithm for maximum coverage over a matroid with optimal approximation ratio.
- Possible extension to arbitrary monotone submodular functions.

### **Questions?**
